The Urban-Rural Happiness Gradient Across Countries: City Unhappiness is Common (Despite What Economists Say)

Tuesday 8th September, 2020 14:05

This study shows, for the first time, that city unhappiness is common across the World. The finsing is important because there are publications manipulating data through cherry-picking (e.g., Glaeser 2011b, Glaeser et al. 2016, Burger et al. 2020) and claiming the opposite, that urban areas are happier. Such manipulation is argualby for ideological reasons. The axioms of economics are that the greater production, productivity, income, and consumption, the better. Urban areas produce most, are most productive, and most income and consumption take place there. Economics' concept of utility is directly linked to consumption, the more consumption, the more utility. While utility cannot be measured, economists appear to try to show that happiness is greatest where economics axioms point to, in cities. Sociological, psychological, and neurological evidence is ignored and research having little to do with reality is produced. Present study is correlational, not experimental, and causality cannot be claimed. Because of the limited cross-cultural comparability of SWB measure, when interpreting results, the focus should be on within country SWB differences across urbanicity, and not on comparing cross-country effect sizes.

We know that in many countries there is a so called "urban-rural happiness" gradient Berry and Okulicz-Kozaryn (2011), where happiness raises from lowest in largest cities to highest in smallest places. The gradient is non-linear, the very largest cities are markedly less happy than all other areas in a country: New York City (Okulicz-Kozaryn and Mazelis 2016, Senior 2006), London (Office for National Statistics 2011, Chatterji 2013) Helsinki (Morrison 2015), Bucharest (Lenzi and Perucca 2016), Sydney (cited in Morrison 2011). The goal of this paper is to test gradient across countries using one dataset with uniform variables. This study shows, for the first time, that city unhappiness is common across the World ¹

Intersection of Quality Of Life (QOL) or Subjective Wellbeing (SWB)² and Urban Studies is an exciting area. Academics, policy-makers, administratos, and common people start to pay more attention to QOL/SWB, not just \$. We finally begin to realize, even some economists do (Stiglitz et al. 2009), that money is not everything and it is high time to look at human flourishing: QOL and SWB. But some economists manipulate data through cherry-picking (Glaeser 2011b, Glaeser et al. 2016, Burger et al. 2020) and try to claim the opposite, that cities are happier—the present study provides yet more evidence that economists' thesis of city happiness is false.

The world is experiencing massive urbanization–urbanization is arguably the most dramatic change to our way of life Wirth (1938), Hanson (2015), and what arguably matters most is human QOL/SWB. Hence, the question, how cities affect human condition?

Modern research on the effect of cities on human wellbeing should be founded on extensive classic urban sociological research (Tönnies [1887] 2002, Wirth 1938, Simmel 1903, Park 1915, Park et al. [1925] 1984), which argued negative effect of cities on humans. Quantitative research on the urban-rural happiness gradient dates back to (Gurin et al. 1960, Campbell et al. 1976), who also found negative effect of urbanicity on humans. And over past several decades, several dozen studies mostly found negative effect of urbanicity on human wellbeing as well [blind for peer-review].

Yet most research in the area is about the US, Western Europe, and recently China and handful of other countries. Most studies are conducted in a single country. Hence, we offer the present study using a uniform dataset across countries.

First, we briefly define SWB and mechanisms that are likely to link size of a place to SWB.

¹Most extant research in the area is about the US, Western Europe, recently China, and handful of other countries. Again, there were studies conducted in single countries, but not using a uniform dataset across countries. The three apparent exceptions (Berry and Okulicz-Kozaryn 2009, Burger et al. 2020, Easterlin et al. 2010a) are not exceptions. No study studies the gradient, all use binary urban-rural operationalizations and present simple mean differences for each country and aggregate results to groups of countries in regressions as elaborated later. Last but not least, Gallup data used by Burger et al. (2020) and Easterlin et al. (2010a) are problematic as elaborated later.

²The two, SWB and QOL overlap, but there are important differences, notably QOL is more of an index/aggregate of domains and more subjective, while SWB is subjective mostly evaluation of one's life as a whole–for discussion see Okulicz-Kozaryn and Valente (2019).

1 SWB

3

Subjective Wellbeing (SWB) is an umbrella term for various subjective measures of wellbeing, notably positive and negative affects, happiness, and life satisfaction. Most of the SWB research, including this study, uses life satisfaction measure, which is a global self evaluation of one's life as a whole. This measure is mostly cognitive and not affective—respondent evaluates her life as whole globally (everything, including profesional, personal, family, community, etc). The measure captures everything that is going on in one's life—that's a major advantage of SWB measure over other social and economic indicators aiming at measuring human condition, progress, and development. SWB measure is simply the most comprehensive measure possible dwarfing earlier measures such as income, education, or life expectancy. For review see Diener (2009).

Following usual practice, for simplicity, we use these terms interchangeably: SWB, happiness, and life satisfaction, but specifically we mostly mean life satisfaction as defined above.

SWB measure is also at least adequately reliable and valid and considered good enough for public policy making and public administration (Diener 2009, Stiglitz et al. 2009). And it has been used multiple times in urban research (e.g., Moeinaddini et al. 2020, Mouratidis 2019, Wang et al. 2019, ano 2017, Ma et al. 2017, Wkeziak-Bialowolska 2016, Valente and Berry 2016, Chen et al. 2015).

There are cross-cultural comparability caveats, however, and SWB may not be adequately comparable across countries (Kahneman et al. 1999, Diener 2009). This limitation should be kept in mind when comparing results across countries in the present study. And more focus should be on within-country differences, and this is what this study is mostly about—the difference between smaller and larger places in terms of SWB within countries. We treat each country separately and do not pull the data together. To summarize, one should focus on within-country differences across urbanicity and exercise caution when comparing effects across countries.

2 Urban Definition, Theory, and Potential Causal Mechanism/Pathway

It is useful to start with the theory that would define urbanicity and predict how urbanness would affect SWB. We start with classic urban sociological theory of urban malaise (Tönnies [1887] 2002, Wirth 1938, Simmel 1903, Park 1915, Park et al. [1925] 1984): cities produce superficiality, transitoriness, withdrawal, impersonality, superficiality, deviance, shallowness, anomie, alienation, and cognitive overload.⁴ Sociological theory is not clear at which point urban malaise arises, there is clearly no hard cutoff point, rather, the more urban, the more malaise. There may be a certain threshold though, at which malaise intensifies as hinted at by Fischer (1973): the largest cities, >several hundred thousand. To classical urban sociology city is defined by large population size, density, and heterogeneity (Wirth 1938). To sum up, urbanicity has mostly negative effect on humans, and it is rather a continuum than binary, although a threshold at several hundred thousand may exist where malaise intesifies.

Another indication of coninuity in effect of size of a place on human condition comes from physics, and clearly points to a continuum. There is physical city constatnt of 1.15: double area's population size and many phenomena (crime, gdp, income, patents) increase by 15% (Bliss 2014, Bettencourt et al. 2010, Bettencourt and West 2010, Bettencourt et al. 2007).

We would like to especilly highlight biological/evoutionary mechanism. For over 95% of our evolutionary history⁵ we have lived outside of the cities as hunter-gatherers usually in small bands of 50-80 people (Maryanski and Turner 1992). It only started to slowly change in about 10,000 BC with domestication of animals and agriculture. The first large cities (again,>250k) only started to emerge after 500 BC and there were just handful of them. It wasn't really until after industrialization that large cities started to house noticeable proportion of the population, and only 20th century saw urbanization explosion—in 1800 a mere 1.7% of the world population lived in cities larger than 100k, it slowly increased to 2.3% in 1850, by another 50 years doubled to 5.5% in 1900, and then it doubled again to 13% in 1950 (Davis 1955).

The larger the place, the more the environemnt differs from the habitat in which we have evolved: dense and crowded, ⁶ airport, subwyay or rapid transit, tall buildings in downtowm, etc. And again, while clearly urbanness is a continuum, there is likely a threshold, around several hundred thousand people, when the buildt environment changes significantly. The are at least several significantly different stages of urbanness. There is wilderness, open country, villages, small towns, large towns, cities, large cities, and very large cities. Surely, it is difficult to capture urbanness in its entiterty—most dataset only allow few stages, including the data used here. But the point is that treating urbanness as an urban-rural dichotomy is an oversimplification without much theory to support it.

For a nice discussion and overview of density, crowding and human behavior see ??.

³As this is an observtional study, not an experiment, we don't test causality here, nevertheless it is importat to discuss the potential mechanisms.

⁴Classics argued poor social ties in cities, but see later arguemnts by Fischer and his subcultural theory (Fischer 1995, 1975, 1972).

⁵Per human species evolutionary history, for instance, see encyclopedia Britannica http://www.britannica.com/EBchecked/topic/277071/hunting-and-gathering-culture. For post-medieval history see White and White (1977).

⁶There are striking examples of crowding in largest cities. To be sure, majority of urban population does not live in such extreme crowding, the trend however is in that direction as cities are becoming larger and less affordable. And, again, even eithout extreme crowding, usual population density is related to crime (Bettencourt and West 2010). There is also evidence that density relates to negative consequences: interestingly there is evidence that density impacts pathology more than crowding (?). Yet, it is not only density and crowding, other factors such as social support matter as well (?). Some studies didn't find negative effects of density or crowding and results were mixed (?). While it seems to be reasonable to assume that density and crowding are positivelty related, some studies do not find this to be the case (??). Crowding probably has become more common in recent years as cities are becoming less affordable. Misra (2015), Florida and Schneider (2018), Weinberg (2011), Solari (2019), Schuetz (2019), Kotkin (2013)

The biological/evolutionary perspective can be complemented bu recent neurological evidence. Urban living is unhealthy to human brain (Lederbogen et al. 2011) and urban living contributes to the development of psychosis (Abrahamyan Empson et al. 2020).

3 The Problem With Economics

There are economists serious about studying happiness, Richard Easterlin and Andrew Oswald among them. But sometimes, economists' interest in happiness is more of a hindrance than help.

Economics is a discipline crippled by its "axioms" (the self evident truths) or "laws." No other social science boasts laws or axioms for a good reason—they do not exist in social world, and so they should not appear in social science. See Feynman (1981) for elaboration.

The bizzare economic axioms that have little to do with reality (Davies 2018), do arguably bias many economic investigations—many economists appear to try hard to force the data to support their axioms, intentionally or unintentionally, but at the end, misleading and flawed research is produced. To economists, by definition (it's the law or the axiom), the more money (income or consumption), the greater the utilty (e.g., Autor 2010):

$$money = utility \approx happiness$$
 (1)

Since utility cannot be measured, it appears then that economists who try to study happiness, think of it as utility, and follow their axiom in their happiness investigations.

For instance, Easterlin Easterlin (2015), Easterlin et al. (2010b) (and many others) found that over time in the long run at country level income is unrelated to happiess: this is the so called Easterlin Paradox. It clearly runs against the sacred economic axiom, and so two economists Stevenson and Wolfers (2013) in the flagship journal of the American Economic Association, the American Economic Review, challenge Easterlin Paradox and present "evidence" to the conrary. Except, that they don't, they study something different—use data at household level or across countries at one point in time and log tranform the data.

Again, we know that cities tend to be less happy than smaller areas. But economists try to argue to the contrary. Why? Again, arguably due to their axioms: money is centered in cities⁷, and so by economic axioms, cities have greater utility, and so they must be happier.

Unfortunately, economists manipulate the sample, or cherry-pick the cases, in order to argue their point. Glaeser (2011b) cherry picked only poor countries for his urbanicity-happiness analysis, and then tries to argue that the relationship holds in general. Glaeser's trick is to say that he finds positive relationship and that the effect is "driven primarily by poorer countries"—which leaves impression as if overall relationship is positive for all countries and stronger for poorer countries. But almost the opposite is true: for most countries the relationship is negative and it is only positive in few cases, typically the the very poorest countries. Glaeser et al. (2016) is an analysis across US counties, where he cherry picks again: retains cities only, drop all other areas.

Then comes (Burger et al. 2020), who appears to piggy back on Glaeser: "In line with earlier research, we found that urban populations are, on average, happier than rural populations in that they return higher levels of happiness."—like Glaeser, Burger et al. (2020) builds his case by focusing on exceptional outliers, mostly poor African countries.

To summarize, many economists appear to be misguided by their unrealistic axioms, and some end up producing misleading and flawed research, notably: Stevenson and Wolfers (2013), Glaeser (2011b), Glaeser et al. (2016), and Burger et al. (2020).

Curiously, some economists who do happiness research are sceptical about it at the same time, and do not consider happiness worthy investigation (e.g., Deaton 2013, Glaeser et al. 2014, 2016). Economists in general tend to consider other social sciences as inferior (Economist 2016, 2014, Naim 2016, Fourcade et al. 2015).

4 What We Know So Far: The Literature

Most research on the urbanness-happiness relationship points to the urban-rural happiness gradient, where happiness raises from its lowest level in largest cities to the highest level in smallest rural areas (e.g., Campbell et al. 1976, Berry and Okulicz-Kozaryn 2011, Office for National Statistics 2011, Morrison 2011, Okulicz-Kozaryn and Mazelis 2016, Senior 2006, Chatterji 2013, Morrison 2015, Lenzi and Perucca 2016, Okulicz-Kozaryn and Valente 2020). [blind for peer review]

Yet, most research has been conducted in the US or Western Europe, and there are only three cross-country investigations: Berry and Okulicz-Kozaryn (2009), Easterlin et al. (2010a), Burger et al. (2020).

Easterlin et al. (2010a) focuses on effect of economic growth by urban-rural and only a small part of the study is about urban-rural differences in SWB, and their results are much like Berry and Okulicz-Kozaryn (2009), which finds that in developed countries people are less happy in cities. All three studies so far are limited.

The present study is the first one to study the urban-rural happiness gradient across countries. First, there is no gradient in none of the above studies—they all use binary (or three category) operationalizations, urban v rural. They also mostly present simple mean

⁷Production, productivity, income, and consumption inccrease with population size Glaeser (2011a, 2007), Glaeser et al. (2001), Rosenthal and Strange (2002, 2003, 2008).

differences for each country and aggregate results to groups of countries in regressions. They fail to control for necessary predictors of SWB. In addition, there are critically serious problems with Gallup data.

Easterlin et al. (2010a) is a serious academic peer-reviewed research, and does acknowledge Gallup's limitations and attempts to address them. Burger et al. (2020), on the other hand, appears to be a mere for-profit/consulting advertisment for Gallup. As Davies (2015) put it, it's not happiness research, it's "happiness industry."

There are multiple problems with Gallup data. First, it is not meant for research but for commercial use–Gallup charges \$30,000 for access (per one year!). Second, urbanicity classification is twofold less precise than in WVS: 4 v 8 categories. Third, while WVS uses precise population size numeric cutoffs, Gallup uses fuzzy concepts such as "rural area", "small town or village", "large city". Fourth, (and this compunds third problem) Gallup uses self-reports of urbanicity, which is highly subjective and problemtaic in this case—many, if not most people, would likely classify themseves completely arbitarily into "rural area" v "village" and so forth. WVS uses interviewer's information about the place. Fifth, apperntly much of data are missing—easterlin notes that in 14 countries "rural area" responses were exceptionally low. Also, about half or world population is urban, but burger reports that in their dataset only about quarter of respondents report rural residence.

Urbanness or urbanicity is a degree, not dichotomy. Srikingly, burger say that there is a uniform way to measure urbanicity, which is a mere 3 categries: 1) Cities, 2) Towns and semi-dense areas and 3) Rural areas; but they dont even use that in the body of the paper and stick with dichotomy.

5 Data And Model

We use http://www.worldvaluessurvey.org/wvs.jsp, which is representative of multiple countries, and as elaborated in previous section, is much better suited for the study than an inadequate and poorly designed Gallup data. The variables are listed in table 1. Country codes and descriptive statistics are in SOM (Supplementary Online Material).

SWB question reads "All things considered, how satisfied are you with your life as a whole these days? Using this card on which 1 means you are "completely dissatisfied" and 10 means you are "completely satisfied" where would you put your satisfaction with your life as a whole?"

Urbanicity is operationalized with WVS variable X049—note that it is objective and recoreder by reviewer, not respondent. There are eight categories ranging from <2k to >500k. This is important advantage, because as elaborated earlier urbanicity or urbanness is a continuum, not a binary urban v rural. We conduct analysis using a set of dummy variables for all eight categories (leaving out the base case) in the SOM. However, for simplicity and ease of expesition we present simplified results in the body of the paper using three categories only. In other words, this study will use 8 categories of urbanicity, and summarize results for ease of presetation with 3 categories.

Because in many countries, there are either no observations or few observations in the first two bottom categories -2k and 2-5k, we combine them together for the analyses in the main body of the paper. These two categories together proxy environment free of city characteristics, natural environment most closely resembling human natural habitat where we have evolved, and it includes: wilderness, open country, and small villages. The other critical category based on earlier review of theory is large cities, again, there is likely to be a threshold at several hundred thousand, hence we use the top category on WVS variable X049 500k- to proxy large cities. Such places, are the least resembling humans natural habitat and are mostly consisting of man made objects such as asphlat, concrete, glass, etc, and as per theory as reviewed earlier are likely to be least happy. The third category in our main analyses are places in between 5-500k. In other word, we are exploring the urbanness gradient fully in the SOM, and only then in the second step, for ease of exposition, but preserving original findings and patterns, in the body of the paper we simplify it by looking at two extremes -5k v 500k-. The cutoffs for the two extremes are important and must be driven by the theory, it cannot be say everything upto 20k (100k, etc) v more than 20k (100k, etc) as in some other research. A place never changes abruptly from rural to urban at some cutoff, it is a continuum, it can be simplified to carefully chosen extreme categories, but one must always start with the continuum.

And because this aggregation or simplification into 3 categories is still somewhat arbitrary, we present alternative specifications in SOM in addition to the full 8-step urbanness gradient.

Table 1 lists control variables used in the body of the paper.⁹

⁸Gallup charges \$30,000 per year for use of these happiness data (author's email inquiry)–private corporations are making fortune from tax dollars and students tuition–scholars should resist corporatization of academia (Mills 2012a, Cox 2013, Mills 2012b, Catropa and Andrews 2020, SCHMIDLIN 2015), and corporatization of happiness research (Davies 2015).

⁹There are models with additional controls in SOM (Supplementray Online Material).

Table 1: Variable definitions.

name	description
happiness	"All things considered, how satisfied are you with your life as a whole these days?" 1="dis-
	satisfied" to 10="satisfied"; WVS
place size	"OBSERVATIONS BY THE INTERVIEWER; Code size of town where interview was con-
	ducted"
education	"Highest educational level attained"
income	"Scale of incomes"
class	"Social class (subjective)"
health	"State of health (subjective)"
postmaterialist	"Post materialist index "
god important	"How important is God in your life? Please use this scale to indicate- 10 means very important
	and 1 means not at all important."
religion important	"WVS2000: For each of the following aspects, indicate how important it is in your life.
	Would you say it is: EVS1999: Please say, for each of the following, how important it is in
	your life. Religion"
autonomy	"Autonomy index"
freedom	"Some people feel they have completely free choice and control over their lives, while other
	people feel that what they do has no real effect on what happens to them. Please use this
	scale where 1 means 'none at all' and 10 means 'a great deal' to indicate how much freedom
	of choice and control you feel you have over the way your life turns out."
trust	"Most people can be trusted"

In choice of controls we generally follow (Okulicz-Kozaryn and Valente 2020). There are specific controls worth discussing.

Young, single and childless persons and young men with tertiary education are relatively more satisfied with urban areas as place of residence (Carlsen and Leknes 2019). Income, class, and education are important controls–not only predict greater swb, but also confounded and higher in cities.¹⁰

One great advantage of city living that is often forgotten is freedom "City air makes men free (Stadt Luft macht frei)" Park et al. ([1925] 1984, p. 12)¹¹, hence we control for freedom.

Likewise, trust is important, it predicts swb, and it is lower in cities (Milgram 1970).

Health is a key predictor of swb, and also note that subjective health measure used here is a reasonable measure of actual health (Subramanian et al. 2009).

We use a standard OLS regression with robust standard errors. We treat the 10-step happiness variable as continuous. Ordinal happiness can be treated as a continuous variable (Ferrer-i-Carbonell and Frijters 2004). OLS has become the default method in happiness research (Blanchflower and Oswald 2011). Theoretically, while there is still debate about the cardinality of SWB, there are strong arguments to treat it as a cardinal variable (Ng 1996, 1997).

6 Results

While, again, we do concern ourselves with the coninuum, the urban-rural happiness gradient, results are in the SOM, here for ease of exposition, we only preent the contrast between smallest, medium, and largest places. There is a considerable tradeoff in this study between ease of presentation and elaboration as there are dozens of countries and presenting different specifications would result in unwieldy presentation—additional specification are in SOM. Here we just present one model that is full including all necessary and some additional controls (yet not over staurated where too many variables result in too many missing obs)—we use here model with controls listed in table 1 **TODO chec with dofile** also the mdel presented here uses just 3 categores, -5 (base), 5-500, and 500-; we are interested in comparison between -5 v 500- because this is aaccording to theory: evolution/ingroup v most unnatural (as this data allows).

TODO have couple paragraphs interepting these regressions

¹⁰where i dicuss controls in data and to literature where i slam burger and indeed as shown later comparing unadjusted means results in cities being happier notably due to confounding of higher income education and class–see appendix for tables with and wohou controls

¹¹It originated in the Middle Ages, and it meant freedom from feudalism, non-feudal islands in a sea of feudalism (Harvey 2012).

Table 3: exT3-3

5/25: 80 perc less happy! mostly easyern post soviet copy from below lol 12

Results in table ?? are remarkable. In most countries large cities are less happy than small settlements. Remarkably, without exception, in no developed country city is happier than smallest areas. The only four countries where people ar ehappier in large cities are:

and the point is that the only ones that are sig and positive are wiers small poor and most miserable countries except india which is a big puzzle

TODO repreat it multiple times! TODO add NOR NLD so the conclusion is that in all develped countries AUS, CAN, DEU, ESP, ITA, NZL, SWE, USA, cities are less happy ¹³ in vast majority of countries effect in ngeative, only positive in these 4: russia, moldova and albania are all post soviet countries, they are likely to still be very centralized where power opportunity and resources are located in large cities; india is clearly an outlier here and we dont have a good explanation **[blind for peer review]**

make the biggest swb gaps by country key focus of paper :) **TODO!!!** this research focus on specifics countries esp where urb rural grading is greatest!

yah i think just one table! refer though to bivairate in appendix and say this in footnote and or app Table ?? shows

¹²note result for VEN should be interpreted with caution this is the main difference with table ?? and probably has to do with the fact that there are only 60 obs on the base case category. Other results are similar between the two tables.

¹³at least in less elaborate specs, but even in most elaborate even if insig, still neg

resuls of regression of swb on place size dummies (controlling for year dummies), which essentially differences in means for each size category. Results are mixed, but large cities (500k-) and even medium sized (100-500k) are often happier than the smallest category (the base case or reference category, -2k). Usually differences are small to moderate, about .5 (on 1-10 swb scale), but sometimes large, larger than 1. Do mention the extremes and think about why-but we do not have explanation for those.

This is what the literature reports, tht results are mixed, in some cases cities are happier, in some cases they are not. A key finding of this study is that once we properly control for key predictors of swb, almost uniformly large cities (500k-) are less happy than the smallest settlements (-2k). Results are shown in table ??.

7 Conclusion And Discussion

Throughout most of our evolutionary history, humans have lived in small homogenous groups with low density. As hunters gatherers humans lived in small bands of 50 to 80 people, later on in simple horticultural society in groups of 100 to 150 people, and in more advanced society these groups reached five to six thousand people (Maryanski and Turner 1992). Hence, unlike other species like ants and bees, ¹⁴ living in heterogenous, dense, and large settlements (city living) is simply unnatural to human beings.

it is not city probelms but city itsef-my paper with jonie the mechanism is important how and why would urbnnnes affect human wellbeing?

; while again we would like to have more gradation at the top of the distruibution, but 500k is a reasonable and adequate cutoff to disinguish a large city from other places. there are no other data better suited for this purpose and we do best we can. And results are conservative—had we have cutoff at 750k or 1m they'd be stronger MY BOOK AND CITIES WHEN CITY IS TOOO BIG.

limitations: Have in paper caveat about cross cultural comparability, see shourjya paper lol

Many countries where no difference— this is still striking and worth reporting and city triumph—one would think cities are the best places to live, people flock there in doves Show graph from UN, and the common narrative is that city is the place to be, and so one would think people are happier there. So finding of no difference is already surprising.

Do visualize results, say a even a small country of 10m and even a miniscule effect of .1 on scale from 1-10 that translates to an effect equivalent to making100k people from most miserable to most happy on swb scale 1-10 if everyone lived in smallest v largest. Small or moderate effect sizes translate into large effects because of the sheets size of urbanization in billions of people.

that graph from inglehart, in developing countries, and as per maslow pyramid, at first one need to focus on necessities such as survival and cities do help; it is remarkable that in all developed countries studied here, cities are less happy!

Why in developed world people are less happy in large cities, but in many developing countries they are happier? There are at least two reasons. In many developing countries life is simply unberable outside of the city lacking necessities such as shelter, foot, water, sanitation, and healthcare. In developed countries, even smallest places have reasonable access to necessities, and they do not suffer from urban disamenities. Also, it may be so that the grass is always greener on the other side—people idealize what is missing or what is rare.

An alarming trend in higher education, and in research in general is corporatization of higher education and research (Mills 2012a, Cox 2013, Mills 2012b, Catropa and Andrews 2020, SCHMIDLIN 2015). This includes happiness research (Davies 2015). "World Happiness Report" (Helliwell et al. 2020) and its chapter about urban-rural gap in happiness (Burger et al. 2020) uses data from a private corporation. Indeed, the report, and its presentation (e.g., that new zealand happiness conference) is largely an advertisement for Gallup. Gallup then sells the happiness data at \$30,000 (per year!)¹⁵—arguably this is not meant for research (most researchers cannot afford it). The goal here appears not to produce knowledge, but to make money—after all the sole responsibility of a business is profit (Friedman 1970).

8 Takaayway for Practice

Humans are worse off in cities (in terms of happiness). But not always what makes us happy is the right thing to do COMPASS PLEASURE ARISTOTLE. Notably, climate change is more important than human happiness, and cities are most environmentally frindly type of settlemt (MEYER). and there are some limited things that can be done to make cities less miserable—we know what makes city happy BALLAS.

perhaps the cleaest takeaway for practice is that we suffer from overpopulation. again, we only need cities because of overpopulation and climate change (Pachauri et al. 2014), not because of production or productivity or consumption premium of cities. In fact, we have too much consumption and we need less consumption Dittmar et al. (2014), Kasser (2003), Leonard (2010). In fact we arguably also need less production and less economic growth Kallis et al. (2012), Kallis (2011), Van den Bergh (2011). While again cities are most environmentally friendly way to squezze human overpopulation (MEYER) to deal better with climate change, cities directly cause climate change by being centers of production and consumption that drives climate change.

but we would need cities less if we had fewer people-contraception, sterilization etc; once there are fewer people, then we can have a meaningful discussion about right city size-cp from book; it is remarkable that there is no discussion about it! how could we have

 $^{^{14}}$ Human nature is unlike that of bees: by one estimate we're 90% chimp and only 10% bee (Haidt 2012).

¹⁵Author's inquiry with Gallup to use their data.

gone so wrong to think that the bigger the better and that there is no limit-cities are balooning-tokyo has about 40m people, and there are many 20m cities; The greatest and largest cities of antiquity, the Ancient athens were 140k and rome was 450k.

Table 7: Icount

10 descriptive stats

like in eb paper maybe also like min and max and everything in app but order somehow anyway but yeah can see diff in mean across categories from bivariate but still median and sd by cat would be useful!

10.1 Limitations

We do not use Gallup data. Some may argue it is a limitation becuase these data cover more countries than WVS. However, apparently Gallup data cost tens of thousands of dollars and we cannot afford it. In fact we'd discourage scientists from paying from tax money to private corporations to do research. Therefore we actually consider it our advantage not to use Gallup data.

Many world countries are missing, using more WVS data in the future as they become available.

right there are limitations, many countries dropped out as they dont habe many people in smallest or biggest areas

Cross cultural comparbility is a caveat, we run separate for each country and ont pool data but still, it should be kept in mind that happiness can mean soemtig different in different countries. likewise world cities are very different, bradth of the study is accomanied by oversimplification.

"There is research in this area which claims that urban-rural differentials might be country-specific and not be generalisable at all (Rees, Tonon, Mikkelsen, & Rodriguez de la Vega, 2017)."

10.2 Urbanicity Definition and results by different definition and sequentail elaboration

we have 3 different operationalizatios of urbanicity: original 8 cat, collapse one way and collapse the other way; and 3 sets of models: bivariate (iwth yr dummies), esentially mean diff betwenn cat; basic set of controls; necessary/important ones; full//extened (one in the body); and there is 4th one over saturated but has most missing obs and hence postponed to the next section.

where i dicuss controls in data and to literature where i slam burger and indeed as shown later comparing unadjusted means results in cities being happier notably due to confounding of higher income education and class

Table 25: exT-3

this one should be in appendix: 2 out of 10 again, but not rporting this this is oversaturated and missing most countries

Table 26: .

Table 27: exT3-4

so i think start with exT4-2 clean and easy and simple; then exT-3 to show detail and robustness

TODO meh yeah i guess drop this first table!!! note that all developed countres are less happy in cities, AUS (insiginifacnt but sig in next table (todocheck!)

p < 0.1; robust std err **Table 29:** exT4-2 OLS regressions of swb on place size, controls (not shown) are: enumerate

in atble ?? several appear happier like BGD, IND, LTU, PAK, ROU, and RUS, when adding more controls and full town cat that disappers except for 4 ctrioes

Results in table ?? are remarkable. In most countries large cities are less happy than small settlements. Remarkably, without exception, in no developed country city is happier than smallest areas. The only four countries where people ar ehappier in large cities are:

Table 31: exT-3; note robustness chech results are in SOM.

and tehre is even one more elaborate model#4 in app with satfin and crime like about **todo count lol** 20/70 neg of all and nly 4/18 of sig are pos about 80 perc are neg :) or 5/21 in exT4-3

and the point is that the only ones that are sig and positive are wiers small poor and most miserable countries except india which is a big puzzle

TODO repreat it multiple times! TODO add NOR NLD so the conclusion is that in all develped countries AUS, CAN, DEU, ESP, ITA, NZL, SWE, USA, cities are less happy ¹⁶ in vast majority of countries effect in ngeative, only positive in these 4: russia, moldova and albania are all post soviet countries, they are likely to still be very centralized where power opportunity and resources are located in large cities; india is clearly an outlier here and we dont have a good explanation **[blind for peer review]**

The limitation of X049 is not only a low top bin for largest cities (500k+), but also about a thrird of values missing. Future research can focus on specific countries using other data or WVS data using X049CS variable, which has country specific sizes of places, which

¹⁶at least in less elaborate specs, but even in most elaborate even if insig, still neg

however are not directly or easily comparable—bins differ across countries and in some cases place is names "major city", "Farm / Mountain / Fishing village," etc).

show distributuion of place size by country!

10.2.1 original 8 categories

10.2.2 0-5k v 500k+

yeah this is following berry, but better have 0-5 so that more obs lol

10.3 Crime and Cost of Living/financial satisfaction

missing obs but here as a robustness check

TO WHERE I HAVE WE NEED TO CONTROL FOR CRIME: Urban unhappiness is not only due to urban problems such as crime and poverty. Cities themselves, their core defining characteristics, size and density, are related to unhappiness (Okulicz-Kozaryn and Mazelis 2016).

yeh so one limitation is lack of crime; so bias on results cities wiuld be happier otherwhise

	Table /1	-		

Table 41: ex1

11.1 very first results

Table ?? shows resuls of regression of swb on place size dummies (controlling for year dummies), which essentially differences in means for each size category. Results are mixed, but large cities (500k-) and even medium sized (100-500k) are often happier than the

smallest category (the base case or reference category, -2k). Usually differences are small to moderate, about .5 (on 1-10 swb scale), but sometimes large, larger than 1. Do mention the extremes and think about why—but we do not have explanation for those.

This is what the literature reports, tht results are mixed, in some cases cities are happier, in some cases they are not. A key finding of this study is that once we properly control for key predictors of swb, almost uniformly large cities (500k-) are less happy than the smallest settlements (-2k). Results are shown in table ??.

Results in table ?? are remarkable. In most countries large cities are less happy than small settlements. Remarkably, in no developed country city is happier than smallest areas (with exception of KWT and SAU-these are middle eastern and oil rich, where cities are glorious indeed)—and they are not developed countries according to IMF or UN anyway neither have very high HDI.
