1 more refined results

1.1 taking into account age bracket and age when having a child

A key variable to explore is age and age when having a child. Parents tend to be much older at 45 v non-parents at 28 in this sample. Then without taking age into account, results could be attributed not to having a child, but to age and other developments that go with it notably much higher income. Hence we pay extra attention to age here.

First we look at distribution–histogram is in figure **??**. A very different distributions emerge–non-parents are mostly around 20 then sharply decreasing to 40 where it levels off at small level. Parents are quite normally distributed with mean and median around 45. Then we create 5 quantiles.

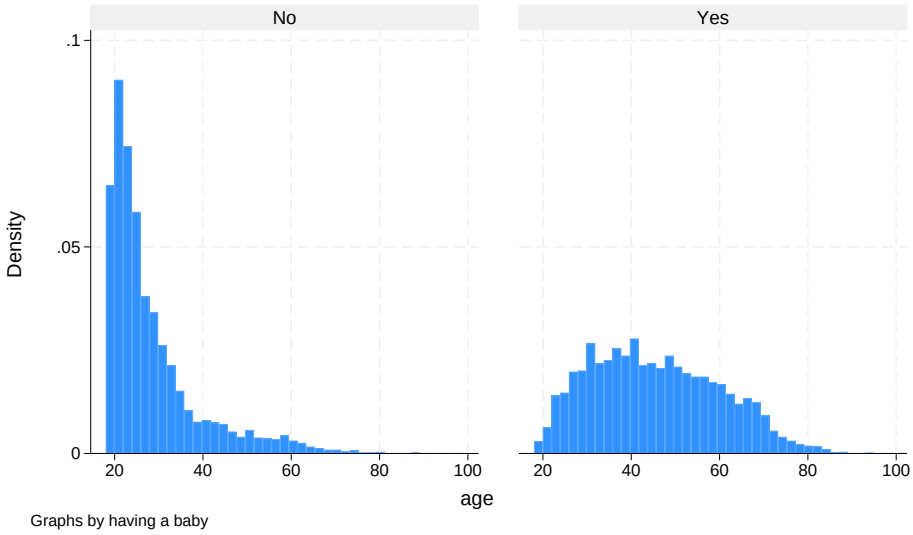

Figure 1: Histogram of age by parenthood.

Finally we turn to the quantities of interest: life satisfaction by parenthood and 5 age quantiles in table below. Note there are good cell sizes at $>$100.

A perhaps surprising news is that its similar for all age grps same pattern–so after all age group does not matter that much for life satisfaction difference between parents and non-parents. Still, there are note-worthy differences: For first 3 quantiles the parent premium is about .1, in 4th it goes up to .15, and in 5th it further increases to about .20. So in short premium of being a parent goes up with age of the parent.

Note this table is also in the body of the ms.

	5 quantiles of edad					
	1	2	3	4	5	Total
having a baby						
No	8.14	8.17	8.34	8.24	8.10	8.18
Yes	8.25	8.26	8.46	8.39	8.29	8.35
Total	8.15	8.20	8.42	8.36	8.27	8.28

Another relevant factor is age of a child–it is very different to have a baby, adolescent and grown up. Keep in mind it is the first child. In table below we tabulate mean life satisfaction by 5 quantiles of child age. Probably as expected having babies in 1st quantile does not yield much happiness. There is .07 increase for adolescents in 2nd quantile; and then gradual drop throught quantile 5, and that is arguably due to aging of a parent. We explore it further in the next table.

```
. table qBabyAge , stat(mean satisfac) nformat(%9.2f)
```

	Mean
5 quantiles of babyAge	
1	8.37
2	8.45
3	8.34
4	8.31
5	8.27
Total	8.35

In table below we show tabulations of mean life satisfaction by parent v non-parent in columns and by 5 quantiles of respondent's age in rows. There is an inverted U-shape for both parents and non-parents with maximum in the middle 3rd quantile. And consistently in all age brackets parents are happier than non-parents by about .1. and the biggest difference being for the oldest parents v oldest non-parents. Thus an interesting finidng is that life satisfaction premium of having a child is greatest in parent's old age, probably as expected .

Note this table is also in the body of the ms.

```
table qAge baby, stat(mean satisfac) nformat(%9.2f)
```

2 initial results

Table 1: Variable definitions.

name	description
life satisfaction	"In general, how satisfied are you with all aspects of your life?"
having a baby	"Do you have children?"
female	female
age	age
health condition	"Would you say that, in general, your health is"
socio-economic strata	"What is the socio-economic strata of your home?"
household size	household size
standard	"Are you satisfied with your standard of living? That is, with all the things you can buy and do"
education	primary, secondary, technical, professional, postgraduate, or none
marital status	"What is your marital status?"
income	"How much on average income?"
poor	"Could you tell me if you consider yourself financially poor?"
relationship satisfaction	"How satisfied are you with the following aspects of your life?" relationship

Then regressions in table 6. C1 and c2: best to have babies in 20s or early 30s. Health and age in c3 really weakens the relationship and income in c4 kills it alltogether. So then we explore interactions with income.

Table 6: OLS regressions of `life satisfaction`.

I generate a dummy for good income: 1 if income>1SMMLV

recode promedioingresos (0 1 =0)(2 3 4 5=1),gen(incGood)

and interact it in figure 2. The intersting result, and probably expected, is that as respondents get older income matters more for happiness from babies, especially in category 4, early 30s, for last category, late 30s and 40s there is little difference between rich and poor just as is the case in category 1, the teenagers.

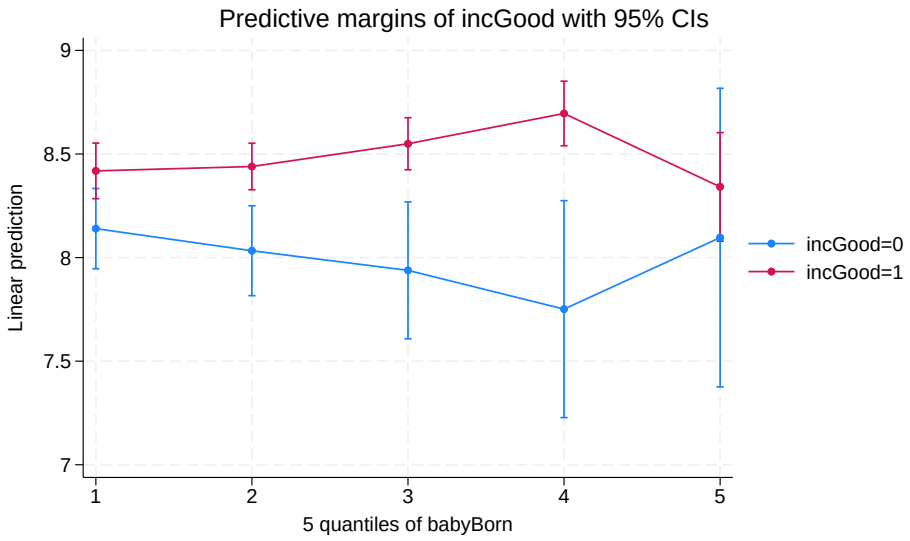

Figure 2: marginsplot

2.3 $< 2024 - 04 - 24 Wed >$ (first try; preliminary! need to do more thinking and double checking)

In table 7 in column a1 bivariate regression (incl year dummies as all do) having baby (dummy) improves happiness by .16. In a2 adding interaction with female shows that actually males happier with babies! Also visualized in figure 3. Interestingly for females the relationship is quite flat–not much increase in happiness if has baby–just from 8.2 to little less than 8.3. But for males increase is from little less than 8.2 to little more than 8.4. There was some literature I guess that mothers were actually less happy hanging out with babies than with friends (not sure about fathers).

Adding age and health in a3 doesnt change the interaction of baby with female. In a4 estrato decreases effect size of the interaction. Controlling for size of household in a5 doesnt change it.

But then in a6 security "You feel your neighborhood is safe?" actualy increases eeffect size on the interaction–security is something to explore further with respect to babies and females!!

Finally in a7 addition of income kills the significance on the interaction. Like security, income is something to explore with respect to babies, which I do in next table.

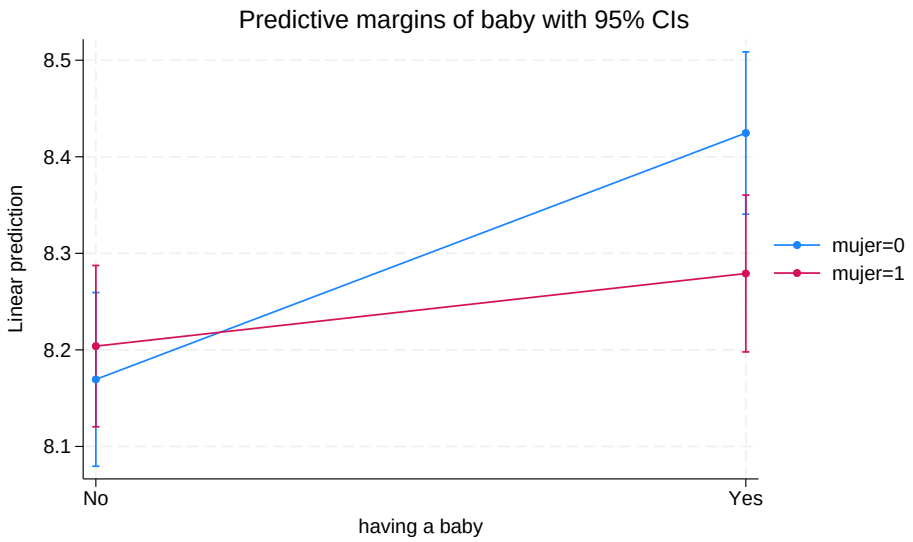

Figure 3: marginsplot

Results now in table 8. I generate a dummy for good income: 1 if income>1SMMLV
recode promedioingresos (0 1 =0)(2 3 4 5=1),gen(incGood)
and interact it with having a baby, and indeed as expected, having baby and good income is more happiness than having baby and bad income in column b1, also visualized in graph 4. With bad income (no income or less than 1 SMMLV)–there is no difference baby or no baby; but with good income, mmore than 1 SMMLV, having baby produces more happiness–also visualized in figure 4.

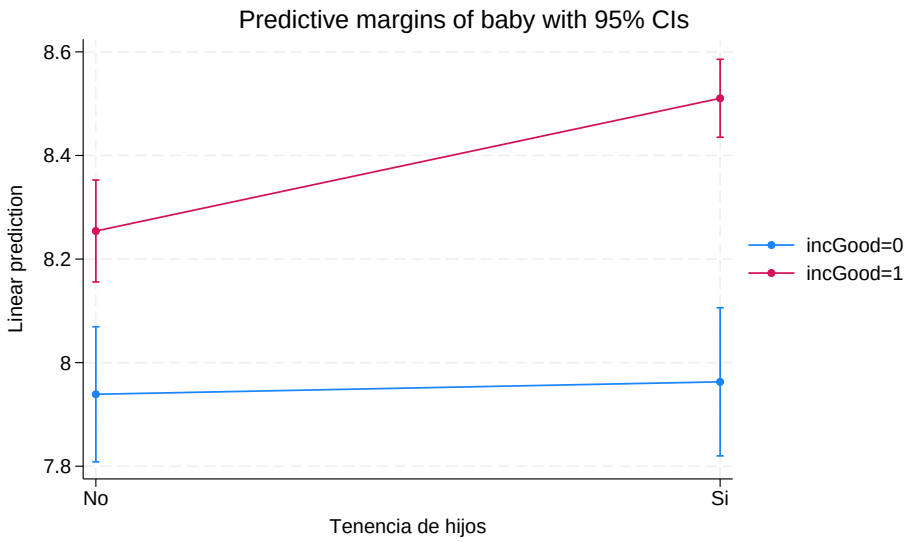

Figure 4: marginsplot

And then combining everything together in column b2: baby, female, and good income; also visualized in graph 5. This is now 3-way interaction and little cumbersome, but interesting. Not having babies (No on x-axis) all groups are closer to each other on the left than having babies on the right–babies magnify gender and income differentials. Starting with males with bad income (blue line): they are least happy with or without babies, but even less happy with babies. Males with good income (red) are in the middle on happiness without babies, but having babies they are the happiest of all–similar to females with good income (yellow line). And in the middle (green)–females with bad income, only slightly happier with babies.

Another interesting thing–females (green and yellow lines) improve only slightly having babies (the 2 slopes are parallel); but for males the story is very different and it depends on income and is magnified by babies. Males without babies only about .2 or so different in happiness based on income like 7.9 v 8.1 or so; but with babies the difference is about .8 on 1-10 happness scale, like 7.7 v 8.5. Big difference.
