Geography of Energy, Vitality, and Happiness Across US Counties (from X/Twitter data)

Wednesday 4th November, 2026 15:06

We use human expression on X (Twitter) to study energy, vitality, and happiness across US Counties. We use 3 metrics measuring energy/vitality: having energy, positive functioning, and vitality; and 6 measuring happiness: life satisfaction, happiness, peace with thoughts and feelings, expressing optimism, purpose in life, and having hope. Cronbach's Alpha scores of 0.85-0.92 indicate high internal consistency and reliability of our novel scales. This is the first study of geography of energy/vitality, where we find a very clear urban-rural gradient with energy/vitality raising from low in large counties to high in small counties. Energy/vitality may be actually more important than happiness or at least as important, and it is striking that we know nothing about its geography. There is literature, on the other hand, on geography of happiness–cities tend to be less satisfied with life. We confirm this finding, but overall on an index and other happiness measures, we find an important qualification. It is not the very smallest counties in the 1st population decile that are the happiest, but small counties in deciles 2-6 (5-37k). The very smallest counties in 1st decile (<5k) are actually the least happy along with the largest counties in 10th decile (>205k). While X wellbeing expressions tend correlate quite highly at about .6 with survey data, operationalizations have limitations and geotagged tweets over-represent certain sub-populations.

HAPPINESS, VITALITY, ENERGY, WELLBEING, FLOURISHING, URBAN, RURAL, URBAN-RURAL, NATURE, TWITTER/X

1 Introduction

Terms SWB (subjective wellbeing), happiness, and life satisfaction are usually used interchangeably in happiness and social indicators literatures. But specifically they mean rather cognitive global subjective self-evaluation of one's life as a whole rather than momentary affective happiness. Here it is rather the latter, momentary affective happiness, as human expression is recorded via tweets on X.[1]

Much ink has been spilled on geography of Subjective Wellbeing (SWB), including in the US, in particular there are studies across counties (e.g., Okulicz-Kozaryn and Mazelis 2018, Winters et al. 2015, Okulicz-Kozaryn et al. 2024), and across urban rural continuum (Okulicz-Kozaryn 2024, 2023, Okulicz-Kozaryn and Valente 2020). Major findings have been that humans are less satisfied with their lives in populated dense North East, but also in poorer Midwest, and some of the lowest life satisfaction scores in addition to largest cities such as NYC and Philadelphia, have been recorded in South, in particular in poor Alabama, Mississippi, and Louisiana. Greatest life satisfaction, on the other hand, has been found in sparsely populated North and West, in states such at Nebraska and Utah, but not so much in overpopulated California (Schkade and Kahneman 1998).

These were happiness and geographic literatures. One limitation of these literatures is sole use of survey data such as GSS and BRFSS and typically just one survey item about life satisfaction such as "How satisfied are you with your life as a whole?" But human wellbeing can be measured in many other ways. Here we use human expression on X (Twitter) across about 3k US counties using 9 metrics: 6 measuring happiness, and 3 measuring energy/vitality. This is the main contribution of our study to expand on measurement of county and urban-rural wellbeing. In the process of doing so we also contribute by connecting happiness and geography literatures (summarized in Okulicz-Kozaryn 2023, Okulicz-Kozaryn and Valente 2020)[2] with X literature, which seems to be mostly in computer science (or computational social science, etc).

[1] Discussion of reliability and validity of twitter data is postponed to section "Data."

[2] For elaboration see Ballas and Rijnks (2023), Ziogas et al. (2023), Weckroth et al. (2022), Ziogas et al. (2020), Ballas (2013), Knies (2026), Sørensen (2024, 2014), Lenzi and Perucca (2022, 2020, 2016c,a,b).

2 X geography of wellbeing literature

There is a quite separate X (Twitter) literature, that started around 2010 shortly after Twitter launched in 2006. One early example on overall geography of X is widely cited Leetaru et al. (2013), but it does not study happiness nor energy/vitality nor any other wellbeing metrics. Various subsequent studies did measure broadly defined wellbeing including energy/vitality and happiness, but they differ in important ways from our study except pioneering Mitchell et al. (2013) that we discuss towards the end of this section.

There is an interesting and related doctoral dissertation (Gupta 2018), but analyzes wellbeing geographies in UK. Chai et al. (2023) produced "twitter Sentiment Geographical Index (tSGI), a location-specific expressed sentiment database with SWB implications", but it doesn't really analyze energy/vitality nor happiness and has a global, not the US, focus.

There are neighborhood level studies in NYC studying happiness and poverty (Tan and Guan 2021) and proximity to parks (Plunz et al. 2019). And one study in Detroit analyzing happiness and neighborhood conditions (Park et al. 2021). And another study analyzing happy tweets, healthy food references, and physical activity across neighborhoods in Salt Lake City, San Francisco, and New York (Nguyen et al. 2016). Another study analyzes sentiment across spatio-temporal dimensions (land use and times of the day) across Massachusetts (Cao et al. 2018).

Then there are several studies that are closer to ours. Hollander and Renski (2022) studies cities, like us, but unlike us excludes rural areas, and only analyzes 50 declining cities matched with 50 growing/stable cities using only 300k tweets.

Hu et al. (2019) may seem similar to our study as it broadly asseses sentiment and positive emotions across us counties, but it is quite different. Their approach and framing are very different. Rather than focusing on geography of wellbeing like us, they explore tweeter topics and correlations in space. Rather than energy/vitality or happiness, they study various topics such as birthdays, parties, and great time on Sunday and focus on spatial correlations rather than levels.

The closest to what we do is Mitchell et al. (2013)–its focus is on geography within the US, but they study states (we study counties), and while they also study some cities like us, it is a limited set. Our data covers virtually all of the US including rural counties. They only have 80m words generated in 2011 on X, and we have >1b tweets 2013-2019. While they also show some results for all of the US in their map in figure 5, it is difficult to read for less populated areas. Another limitation that we improve on is the use of multiple energy/vitality and happiness metrics as opposed to just one happiness metric in their study. Also note the Atlantic article that discuss the arxiv version of their study.[3] We discuss Mitchell et al. (2013) more as we present our results. Note that Mitchell et al. (2013) is one of the pioneering studies done over 10 years ago.

Last, but not least there is an arxiv pre-print (Iacus and Porro 2025) by producers of the data that we use. We both study US geography of happiness, and we both use life satisfaction and happiness metrics. But here similarities end. In addition to life satisfaction and happiness metrics we use 7 other measures. Iacus and Porro (2025) measure rural-urban with USDA ERS 9 Rural-Urban Continuum Codes; we use population deciles. Iacus and Porro (2025) do not focus on any US counties, except 23 most rural counties in their table 4; we focus on largest 20 counties instead. Finally, Iacus and Porro (2025) in addition to geography also focus on politics and income, while we focus just on geography and dig deeper. Thus, despite using 2 variables from the same dataset, our studies differ in critical ways.

Curiously Kjell et al. (2023) shows a map similar to our county estimates in fig 5.1C and cites Jaidka et al. (2020). Jaidka et al. (2020) focuses on comparison of twitter happiness with Gallup data but doesn't analyze by urban-rural. Also, county-level estimates cited in Kjell et al. (2023) are not in Jaidka et al. (2020), not even in supplemetary material, hence it is difficult to discuss. Still, we provide more discussion when we discuss our results. A useful contribution of Jaidka et al. (2020) is a finding that wellbeing X measures correlate well at about .6 with survey data. Another study by Jaidka (Jaidka et al. 2021), like us, analyzes of US counties and urban-rural, but in terms of stress.

Overall, while there is X geography of happiness literature, it either focuses on different geographies (other countries, or other

[3] https://www.theatlantic.com/technology/archive/2013/02/the-geography-of-happiness-according-to-10-million-tweets/273286/

aggregations such as state or neighborhoods) and different (e.g., stress) or more limited metrics such as one measure of happiness only.

3 Data

Data are from `https://dataverse.harvard.edu/file.xhtml?fileId=13094135&version=3.1` and we use data file for flourishing across county-year. Description of the data is at `https://arxiv.org/pdf/2511.03915` (Iacus et al. 2025). HFGI (Human Flourishing Geographic Index) is expressed wellbeing, not a survey measurement of well-being. These indicators capture expressions on Twitter/X, and there are important limitations of such data as discussed earlier.

We drop 2020-2023 due to Covid19 pandemic, but that still leaves us with over 1b tweets. Pandemic has affected US geographies very differently and thus would likely bias our results–low wellbeing would have been attributed to place, while it was due to Covid19. We also dropped county-year-variable cells with <5 valid tweets. If there were very few tweets in a cell, the county-year-variable average could be more extreme than average from larger and more representative sample and thus bias disproportionately the results. We averaged annual scores to one score per county over 2013-2019. There are 9 wellbeing measures, and data covers 2013-2019, having it collapsed for each county over 7 years makes sample size bigger and provides more reliability. For sample description see Appendix. One could frown upon Twitter data, but there are actually reasons to be optimistic. The reliability/validity seems acceptable, again wellbeing X measures correlate at about .6 with survey data (Jaidka et al. 2020). But while acceptable, reliability/validity is probably not high. While some are excited and overly positive (e.g., Karamouzas et al. 2022), others raise important points specifically regarding geotagged tweets.

Geotagged users[4] are not representative of the US population. Number of geotagged users is predicted by younger users, users of higher income, and users in urbanized areas, Hispanic/Latino and black users, and East or West coast (Malik et al. 2015). Very important criticism comes from Jensen (2017) who directly critiques Mitchell et al. (2013) that is very close to our study:

> [...]main issues identified are inferential over-extensions resulting in over-claiming, limitations in the operationalization of key concepts, de facto sampling bias, and a failure to account for the inherent shortcomings of this form of secondary data[...]

We dutifully acknowledge the criticism and find it valid and well-taken and these limitations need to be kept in mind when interpreting the results. But again, we use a $>$100x larger sample of $>$1b than 10m in Mitchell et al. (2013). In general, the reliability/validity seems acceptable. And we use multiple measures with high internal consistency as described below.

3.1 From Twitter data to HFGI (Human Flourishing Geographic Index)

The HFGI was obtained by applying a fine-tuned large language model to geolocated tweets from the Harvard CGA Geotweet Archive. The model was trained to answer questions such as "Does this tweet express vitality?" or "Does this tweet express depression?" For each dimension, its presence and level "low, medium, or high" were identified. These classifications were then converted into numerical scores and aggregated into county-year indicators, each ranging from -1 to 1. The resulting measures capture expressions of specific dimensions of wellbeing in geographically located tweets. Further methodological details and validation experiments are reported in the HFGI data descriptor (Iacus et al. 2025).

[4]For geographic analysis such as ours across counties and urban-rural spectrum one needs geographic location, i.e., geotagged tweet.

3.2 Construction of indices: energy/vitality (eneI) and happiness (swbI)

We start with a caveat: in the choice of variables we mostly used our judgment, there is little literature or agreed upon set of metrics here. But note that the indices were constructed based on the human flourishing indicators that there is some literature about (Iacus et al. 2025, 2015, Curini et al. 2014). Energy/vitality scale is completely new but the items are conceptually related, and have internal consistency valididty confirmed with Cronbach's alpha. And we will also use throught the underlying indicators separately in our analyses.

There is literature motivating some of our choices regarding happiness scale (swbI). Life satisfaction and happiness are clearly close constructs (Michalos 1980, Song and Zhao 2023). Purpose and hope are easy to motivate–there is a lot of research. But innerpeace and optimism are more difficult to motivate. Still, innerpeace may be an essential faucet of wellbeing (Carreno et al. 2021), and optimism correlates with various wellbeing dimensions at about .5 (Shah et al. 2026). Purpose is closely related to or rather even a part of wellbeing (Ryff and Singer 2008, Zika and Chamberlain 1992, Kalaidis 2014, Manson 2015, DePaulo 2021, Ryff 1989, 2014). Hope like optimism is closely related to wellbeing or even a part of it (Manson 2019, Pleeging et al. 2021).

We are encouraged by high Cronbach's Alpha scores that indicate high internal consistency validity or our novel scales. We made indices by simply averaging across indicators–these variables go very well together at high Cronbach's alpha: we have 9 indicators (3 energy/vitality and 6 happiness). 3-item energy/vitality index eneI has a high (good) Cronbach's alpha of 0.85. 6-item happiness index swbI has a very high (excellent) Cronbach's alpha of 0.92.

$$'eneI' = mean('posfunct','vitality','energy') \tag{1}$$

$$'swbI' = mean('lifesat','happiness','innerpeace','optimism','purpose','hope') \tag{2}$$

- Positive functioning. Feeling capable and effective (posfunct).
  low: "Everything feels like too much lately."
  med: "Getting back into a productive rhythm again."
  high: "Handled a dozen tasks today–completely in the zone!"

- Vitality. Feelings of strength and activity (vitality).
  low: "Still recovering from a cold, running on empty."
  med: "Tired but determined to finish this week strong."
  high: "The energy today is unreal–everything feels possible!"

- Having energy. Reports of feeling (or not) energetic (energy).
  low: "Can't seem to get moving this morning."
  med: "A little sluggish but getting things done."
  high: "So full of energy I could run another mile!"

- Life Satisfaction. Satisfaction with one's life as a whole (lifesat).
  low: "My living situation is exhausting and unfair."
  med: "Things are slowly falling into place–can't complain too much."
  high: "Watching the sunset from my porch tonight, feeling truly content."

- Happiness. The text expresses some level of happiness (happiness).
  low: "Mondays always feel endless and gray."

med: "Trying to notice at least one small thing that makes me smile today."
high: "We reached our team goal today–feeling genuinely proud and joyful!"

- Expressing optimism. Optimism about one's condition in the medium run (`optimism`).
  low: "I don't expect much to improve soon."
  med: "Maybe next month will bring better news."
  high: "Things are finally turning around–I can feel it!"

- Peace with thoughts and feelings. General feeling of calm acceptance (`innerpeace`).
  low: "Can't quiet my thoughts enough to rest."
  med: "Learning to take things as they come."
  high: "Feeling calm and centered after a long day."

- Purpose in life. Acting with a sense of purpose (`purpose`).
  low: "I'm not sure what I'm doing any of this for."
  med: "Trying to find direction and meaning in small steps."
  high: "Every action today felt aligned with what I believe in."

- Having hope. Hope about the future (`hope`).
  low: "Hard to see a way forward."
  med: "Things might improve if we stay patient."
  high: "Tomorrow will be brighter–I truly believe it."

4 Results

4.1 Urban-rural gradient

It is hard to believe for urban America that there exists rural America (Hanson 2015), and that there are about 300 counties (whole counties, not villages) with population $<$ 5k. These almost unpopulated counties will be our 1st population decile in our analyses.

We start with urban-rural happiness gradient (Berry and Okulicz-Kozaryn 2011) in table 1 looking at energy/vitality. There is a substantial consistency: the urban rural energy/vitality gradient is raising from its lowest levels in largest counties (color coded with red) to highest levels in smallest counties (green). The only one exception is the `energy` column that only varies across urban-rural at small 0.02, and shows highest level in mid sized counties. An important pattern is that it is not only the very largest counties in the top 10th decile in last row that have lowest energy/vitality, but also other large counties in 7th-9th deciles (37k-205k). `Posfunct` and `vitality` columns show the lowest levels (dark red) not in the very largest counties in the last row "204.9k-10077.3k," but in slightly smaller but still above the median population size rows. So lowest energy/vitality is not only in the very largest counties in 10th decile, but already in 7th decile and higher ($>$36k). Likewise highest energy/vitality is not only in the very smallest counties in 1st decile ($<$5k), but already in 3rd decile and below ($<$13k), and especially in 2nd decile and below ($<$9k).

Note quite large substantive differences. Energy/vitality index `eneI` has a 13% (.35/.31) difference between 1st and 10th deciles. `Posfunct` and `vitality` are even bigger percentage differences.

Table 2 repeats the exercise but for happiness index (`swbI`) and its individual components. Here as expected and shown in the literature (Berry and Okulicz-Kozaryn 2011) in second colored column `lifesat`, life satisfaction raises from its lowest level for largest counties in last decile of population to its highest level for the smallest counties in first decile of population. But this pattern is only observed for this one column.

population 2015 decile	eneI	posfunct	vitality	energy
88-5.1k	0.36	0.37	0.26	0.44
5.1k-8.9k	0.36	0.37	0.27	0.45
8.9k-13.5k	0.36	0.36	0.26	0.45
13.5k-18.5k	0.35	0.35	0.25	0.45
18.5k-25.6k	0.34	0.34	0.24	0.45
25.6k-36.7k	0.34	0.34	0.24	0.46
36.7k-52.9k	0.33	0.33	0.22	0.45
52.9k-92.6k	0.33	0.33	0.22	0.44
92.6k-204.9k	0.33	0.32	0.22	0.44
204.9k-10077.3k	0.33	0.32	0.23	0.44

Figure 1: Energy/vitality index and its dimensions. Note we stick to `lifesat` tag (life satisfaction) as in the original dataset, but again it is rather momentary affective happiness than global cognitive evaluation of one's life as a whole, life satisfaction term used in SWB literature. Estimates with 95% CI are in Appendix.

Overall, in all other columns the pattern tends to be of lowest wellbeing in 1st decile, opposite to what expected from "urban-rural happiness gradient hypothesis" (Berry and Okulicz-Kozaryn 2011). But probably as expected based on the "left behind ruralities hypothesis:" rurality increasingly a periphery, loosing power and voice v urban centrality, being abndoned and disrespected (Hanson 2015, Diamond 2023).

Still, the urban-rural happiness gradient hypothesis (Berry and Okulicz-Kozaryn 2011) somewhat holds, as the counties with highest wellbeing scores are still actually very small[5] counties in 2nd-6th population size deciles (5k-37k), and some of the lowest wellbeing scores are also in the second highest 9th and 10th highest population deciles.

Overall, we find lowest happiness in especially 1st, but also in 10th population deciles and highest in still rural 2nd-6th population deciles. While as expected smaller rural 2nd-6th deciles counties tends to be happier and largest urban 9th-10th deciles counties tend to be less happy, it is unexpectedly the very smallest counties in 1st decile that are the least happy.

population 2015 decile	swbI	lifesat	happiness	innerpeace	optimism	purpose	hope
88-5.1k	0.24	0.15	0.24	0.13	0.15	0.38	0.40
5.1k-8.9k	0.27	0.14	0.27	0.16	0.19	0.41	0.43
8.9k-13.5k	0.27	0.12	0.29	0.16	0.21	0.42	0.44
13.5k-18.5k	0.27	0.11	0.29	0.16	0.21	0.40	0.43
18.5k-25.6k	0.26	0.10	0.29	0.15	0.21	0.39	0.43
25.6k-36.7k	0.26	0.09	0.30	0.15	0.22	0.39	0.44
36.7k-52.9k	0.25	0.08	0.29	0.14	0.20	0.37	0.42
52.9k-92.6k	0.25	0.08	0.29	0.14	0.20	0.37	0.43
92.6k-204.9k	0.24	0.07	0.28	0.13	0.20	0.36	0.42
204.9k-10077.3k	0.24	0.06	0.28	0.13	0.19	0.35	0.40

Figure 2: Happiness index and its dimensions. Estimates with 95% CI are in Appendix.

Again, `lifesat` column is as expected in the literature, and do note huge urban-rural happiness gradient change all the way from .06 for 10th decile to .15 for the 1st decile, >2x difference. But `happiness` is very different from lowest in smaller counties to larger in larger counties (but not very largest), slightly an inverted U-shape with maximum at 6th decile (26k-37k) and `optimism` is very similar. `Hope` has a clear inverted U-shape with maximum at 6th decile and minimums at 1st and 10th deciles. Overall from the happiness index (`swbI`) (and `innerpeace`) happiness has its home not in the very smallest counties <5k, but still in rural counties <18k.

6th decile (26k-37k) scores highest on `happiness`, `optimism`, and `hope`.[6] Hence, for these specific measures there is evidence of inverted U-shape: highest happiness is around median population size and lowest in smallest and largest counties.

[5] Do keep in mind that a US county is large land area, median is at 1.6k sq km, so about 40 by 40 km square. 30k people on 40x40 km square is very rural.
[6] Along with 3rd decile.

4.2 Across counties

We turn to mapping.[7] Energy/vitality index (`eneI`) is in figure 3.

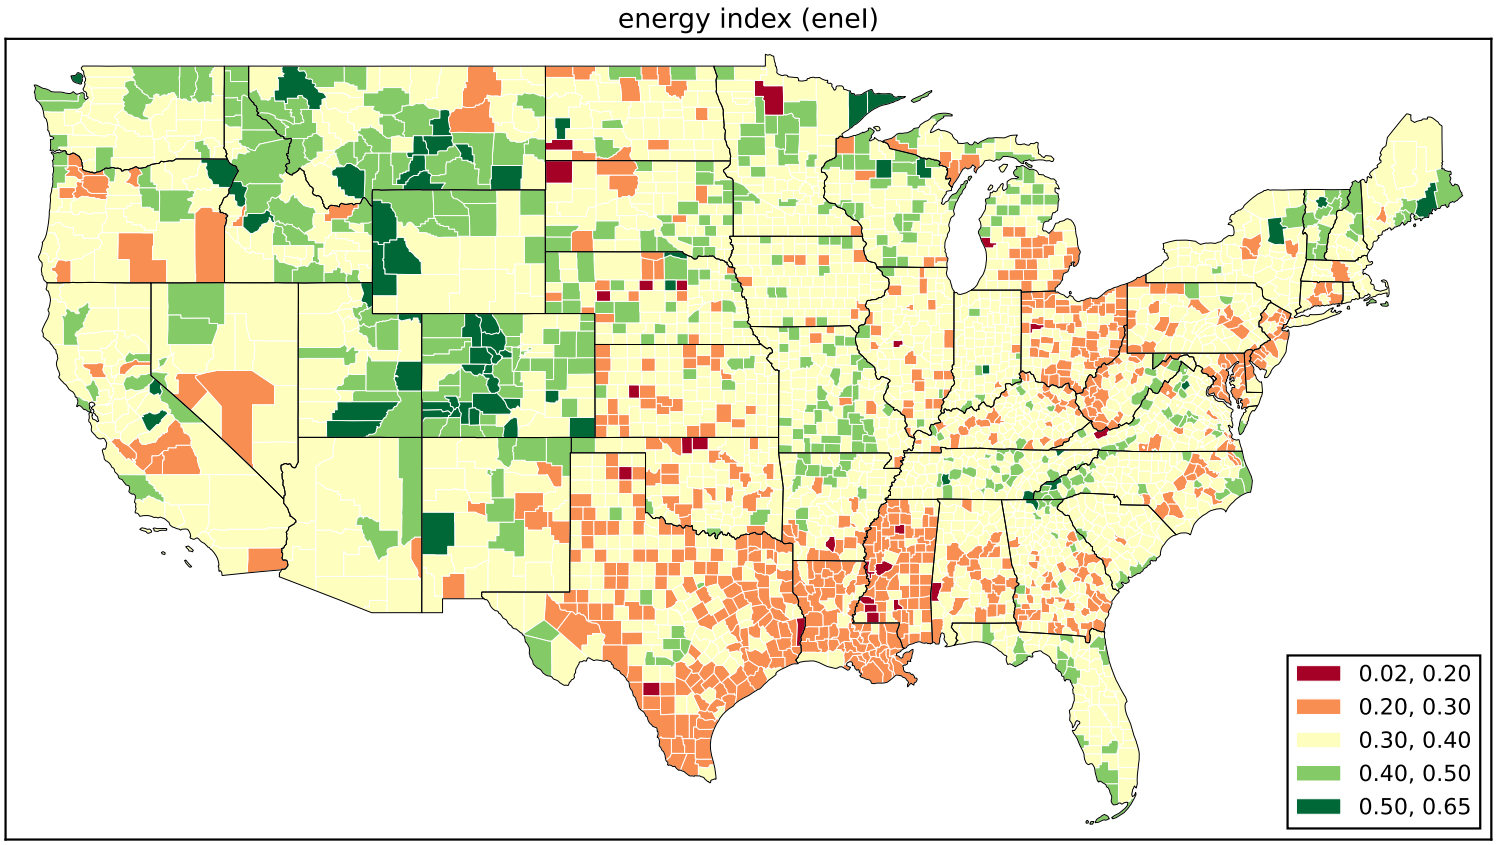

Figure 3: Energy/vitality index (`eneI`).

South does not surprise. As expected, the energy/vitality is low in South: especially in Mississippi and Louisiana, but also in most parts of Texas and many in Alabama and Georgia. Second comes Midwest,[8] no surprise there either. Most of Ohio is low on energy/vitality, and then much of Pennsylvania, West Virginia, and South Michigan (North Michigan is high). Also, much of Oklahoma and Kansas are low on energy/vitality. On West coast, perhaps surprisingly, much of Oregon is low on energy/vitality.

As opposed to dull South and Midwest, there is definitely more energy/vitality in North East, for instance in New Jersey–one would think. But our results disagree–both Midwest and North East are low on energy/vitality, second only to South. Dull and low energy South does contrast with upbeat and high energy North East–it is just that the energy may not be that good in North East after all–arguably stressed and neurotic–we speculate based on anectodal evidence as one of the authors lives in New Jersey. This concludes our general list of low energy/vitality states, but do note many red spots throughout the US and in other states. In appendix we have a top and bottom 100 ranking tables including index components. Also in appendix are more detailed maps with more color bins.[9]

Turning now to high energy/vitality: in general in West and North but not coastal/Pacific West: not Oregon, neither California as expected (Schkade and Kahneman 1998). Colorado seems the highest energy/vitality, but also Utah, Wyoming, Montana, and Idaho.

The happiness map in figure 4 broadly agrees with energy/vitality map in figure 3, and the correlation between the two is .83, for a scatterplot see appendix. There are few differences, however, for instance, Tennessee, Arkansas, and Missouri have more happiness

[7] As maps show, it is only contiguous US, but in other analyses there were few additional observations from Alaska and Hawaii.

[8] And Northeast in next paragraph.

[9] They are similar, so we prefer the simplified exposition presented here. In the more detailed maps, while the extremes remain the same, dark red and dark green, there is much more gradation for mid-levels from light green through yellow to light red.

than energy/vitality. North East, too, to some degree, except New Jersey that is equally unhappy as it has low energy/vitality. As opposed to energy/vitality map, the happiness map is not entirely new.

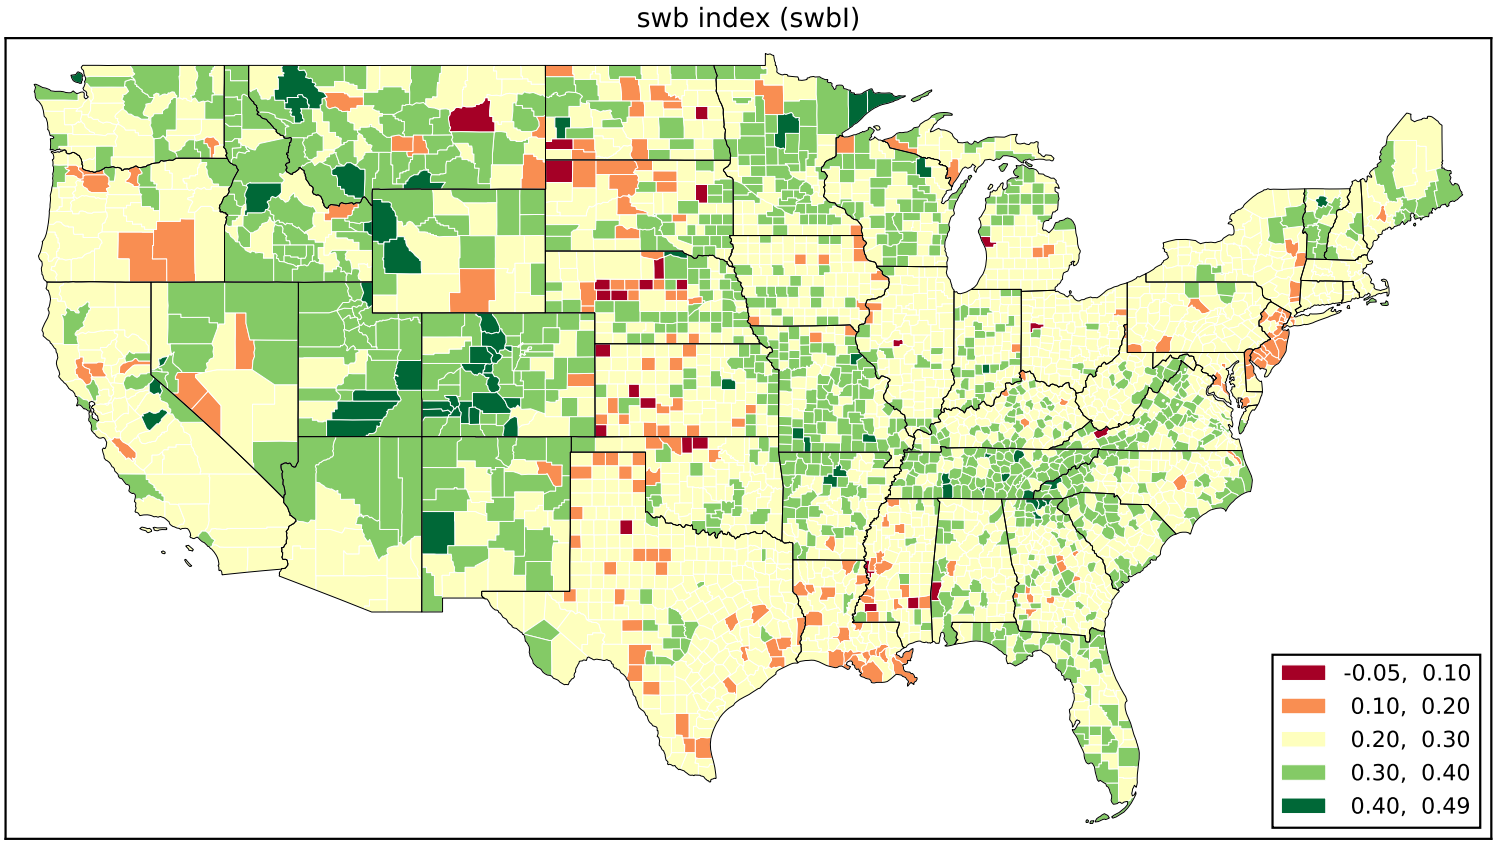

Figure 4: Happiness index (`swbI`).

Results in figure 4 broadly agree at state level with Mitchell et al. (2013). Much of the results in our figure 4 also seem to agree at county level, but it is difficult to say as our map averages at county level, while Mitchell et al. (2013) map closer to actual tweet locations and there are multiple points per county and it is difficult to estimate the average.[10]

Kjell et al. (2023) shows a map similar to our county estimates in figure 5.1C citing Jaidka et al. (2020). It looks like their sample of 1.5b is close to ours. But the results are different possibly due to their "interpolation of missing counties provided through a Gaussian process model using demographic and socioeconomic similarity between counties" (Kjell et al. 2023, fig. 5.1C caption): Alabama, Louisiana, and Mississippi are not unhappy, neither is North East, but Midwest is least happy (we find it unhappy but not as unhappy as Louisiana and Mississippi).

But maybe the most striking difference is that urban counties marked in their figure 5.1C with city names all appear to be the very happiest counties of all (dark green). Except Los Angeles and Miami (2nd shade of green, still very happy), Phoenix (yellow; average happiness), and per New York and New Orleans we cannot really tell as the black city dots cover polygons. Curiously, World Happiness Report and Gallup[11] argue urban happiness despite data showing the opposite–see discussion in Okulicz-Kozaryn and Valente (2021).

[10]Note that there is also an an Atlantic article that covers the arxiv version of their study: `https://www.theatlantic.com/technology/archive/2013/02/the-geography-of-happiness-according-to-10-million-tweets/273286`.

[11]For instance see `https://news.gallup.com/opinion/gallup/315857/degree-urbanisation-effect-happiness.aspx`.

4.3 Zooming in on the largest cities

Figure 5 shows wellbeing metrics for 20 largest counties. It is important to keep in mind that all data including population pertains to a county, not city, for instance Santa Ana city is only about 300k but Orange county is about 3m. Still, we are using cities for ease of interpretations. First, we summarize all indicators as overall happy or unhappy as for most counties there is a clear pattern. First 4 colored columns are energy/vitality (`eneI`, `posfunct`, `vitality`, `energy`), and subsequent 6 colored columns are happiness (`swbI`, `lifesat`, `happiness`, `innerpeace`, `optimism`, `purpose`, and `hope`).

Happy counties are sunny places, but outside of unhappy Texas, and many (but not all) coastal like Los Angeles, Phoenix, San Diego, Santa Ana, Miami, Las Vegas, San Jose and Ft Lauderdale. Also happy are cold but coastal Seattle and Manhattan (New York County).

Detroit, Queens, and Houston are the least happy. In addition to Houston, there are 2 other unhappy Texas cities, Dallas and Forth Worth. NYC has all happiness levels: Queens is very unhappy, Brooklyn average, and Manhattan very happy (it may be happy tourists tweeting happy tweets).

There are few interesting nuances. For instance, 3 Texas cities Dallas, Forth Worth (neighbor of Dallas), and San Antonio score poorly on energy/vitality (first 4 numeric columns) but quite well on hope. Queens and Brooklyn are lowest on hope.

At the bottom of the figure, there is comparison to deciles from earlier figures (note that colors differ as they are scaled to current figure). Decile 1 tends to be higher on first three indicators and `lifesat` column, but lower on others.

In appendix we provide a full list of top and bottom counties on energy/vitality index `eneI`. Highest and lowest both energy/vitality and happiness indices tends to be in small counties, below median population size (see appendix).

city	STNAME	CTYNAME	pop.(m)	eneI	posfunct	vitality	energy	swbI	lifesat	happiness	innerpeace	optimism	purpose	hope
Los Angeles	California	Los Angeles County	10.1	0.35	0.35	0.26	0.45	0.28	0.14	0.33	0.18	0.24	0.36	0.43

Figure 5: Energy/vitality and happiness for 20 largest counties. Counties are sorted on population. At the bottom for comparison averages for 1st decile, 2-3rd deciles, and 10th decile.

Again, Kjell et al. (2023) has a map (fig 5.1C) similar to our county estimates, and the results differ. Their map has several large

cities marked on it–and they appear to be the very happiest counties of all (most seem to be dark green). While the black dot marking the city covers most or all of the city-counties, the metropolitan area bordering counties that are clearly visible are very happy, which already is surprising. Except Los Angeles and Miami (2nd shade of green, still very happy), and Phoenix (yellow; average happiness), and unclear New York and New Orleans (small counties completely covered by the black dot), it seems that all these large cities are very happy. They are from West to East: Seattle, Los Angeles, Salt Lake City, Phoenix, Denver, Minneapolis, Chicago, Houston, Atlanta, Washington, and Miami. For instance we have found Houston in table 5 to be unhappy, likewise earlier in county maps all of Houston vicinity wasn't happy.

Note that a caveat here as oposed to decile results earlier is that we have only a single county with limited number of tweets. For details refer to appendix "Descriptive Statistics" section.

5 Conclusion and discussion

We use human expression on X (Twitter) to study energy, vitality, and happiness across US Counties. We use 3 metrics measuring energy/vitality: having energy, positive functioning, and vitality; and 6 measuring happiness: life satisfaction, happiness, peace with thoughts and feelings, expressing optimism, purpose in life, and having hope. Cronbach's Alpha scores of 0.85-0.92 indicate high internal consistency and reliability of our novel scales.

This is the first study of geography of energy/vitality, where we find a very clear urban-rural gradient with energy/vitality raising from low in large counties to high in small counties. Energy/vitality may be actually more important than happiness or at least as important, and it is striking that we know nothing about its geography.

There is literature, on the other hand, on geography of happiness–cities tend to be less satisfied with life. We confirm this finding, but overall on an index and other happiness measures, we find an important qualification. It is not the very smallest counties in the 1st population decile that are the happiest, but small counties in deciles 2-6 (5-37k). The very smallest counties in 1st decile ($<$5k) are actually the least happy along with the largest counties in 10th decile ($>$205k). While X wellbeing expressions tend correlate quite highly at about .6 with survey data, operationalizations have limitations and geotagged tweets over-represent certain sub-populations.

Rurality in the developed world, including the US, is increasingly a periphery, loosing power and voice v urban centrality, being abndoned and disrespected–there is rural disconent, resentment, and shame (Hanson 2015, Fuller 2017, Pospěch et al. 2024, Diamond 2023). This could be one explanation for low scores on some of the metrics for ruralities, especially for the 1st decile of the population size ($<$5k).

It is important to keep in mind that HFGI indictors are about expressed wellbeing, not a survey-like measurement of well-being. These indicators capture expressions on Twitter/X. Not necessarily a limitation, but a caveat to keep in mind when interpreting the results. See important cirticism in Jensen (2017).
